Ankle and Hindfoot Arthrodesis Using ViviGen® Cellular Bone Matrix

Zachary Ritter, DPM, UPMC Susquehanna, Williamsport, PA

CASE STUDY 2

Arthrodesis is used to treat arthritis, deformity, instability, or pain in the ankle and hindfoot. Although this procedure is the most commonly used technique to treat end-stage ankle arthritis, reported success rates vary widely.[1] One bone grafting option for arthrodesis is autograft. Autograft bone can provide the osteoconductive, osteoinductive and osteogenic properties needed for successful bone fusion; however, the retrieval of the autograft can cause pain and site-morbidity to patients.[2] ViviGen provides all three of these properties using viable lineage-committed bone cells. ViviGen contains viable cortico-cancellous bone matrix, cortico-cancellous chips, and demineralized bone and preclinical studies have suggested bone cells might improve fusion over mesenchymal stem cells by providing better bone deposition[3] while remaining in the defect site longer.[4]

The following describes the use of ViviGen to treat a challenging ankle deformity case.

Patient

- A 23 year old obese, Open Reduction Internal Fixation of distal tibial fracture, female patient
- Complained of deformity, pain, and osteoarthritis in right ankle that had been present for six years
- Failed conservative treatments include bracing, physical therapy, orthrosis, and a rocker shoe

Procedure

- Arthrodesis was undertaken to correct a varus deformity (Figs. 1&2)
- Full thickness cartilage loss was observed
- 5 cc of ViviGen was used

Results

- Fusion was achieved by eight weeks
- Preoperative moderate to severe pain decreased to no pain postoperatively
- Patient was full weight bearing at six weeks with a boot and discontinued boot use at eight weeks

Conclusion

- Patient was "very happy" and no complications were observed
- Arthrodesis using ViviGen was successful at inducing fusion within eight weeks (Figs. 3&4)
